Science Plan Appendix

Why this approach?

When NBEP published the *State of Narragansett Bay and Its Watershed*, included at the end of each chapter was a list of data gaps, assessment needs, and research needs. These needs were compiled and organized by the Science Advisory Committee to create a draft Science Agenda (Appendix A). This previous effort was never finalized.

Using this information, NBEP conducted individual interviews with 15 of the 16 members of the Science Advisory Committee (SAC) to discuss their current research, and what research needs they note are needed in the region. NBEP also reached out to partners who were funded by NBEP, or sit on other committees for their opinions as well. Topics discussed were included in a lengthy document, which was then organized by the topic areas of Vision 2032 (Appendix B). At an April 2023 meeting, the SAC voted on the ideas/topics that were most important to them and the results of that meeting were summarized in Figure 2.

Most of the needs identified by the SAC were categorized as synthesizing existing data and collecting baseline and applied data. These steps are essential to creating new projects which are responsive to the information we know, and to understand how the ecosystem has changed.

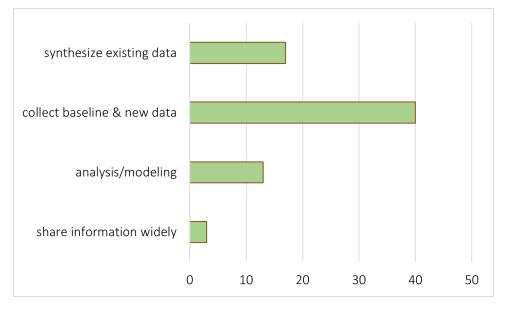

Figure 2. Summary of April 2023 Voting by Topic

Why the limited geography?

The challenge with the topics and questions generated through previous and current efforts is that they are big. They can be addressed anywhere and everywhere in the watershed at the same time. This makes them daunting, both practically and financially. NBEP does not have the funding to fully pursue these questions for every corner of the study region.

NBEP was inspired by partners who have created research collaborations centered around specific geographies to conduct their work. These collaborations include a <u>Living Observatory</u> to study cranberry

bogs, and a Narragansett Bay National Estuarine Research Reserve effort to bring researchers together to study the Succotash Marsh in South Kingstown, RI before, during, and after a massive restoration to the area occurs. These collaborations bring scientists, the public, and managers together into one geography to learn and work together, and share resources.

NBEP focused on four main geographies of the region: urban waters, coastal habitats, upland areas, and the mainstem of Narragansett Bay. Using information gathered in April 2023, NBEP sorted the topics into geographies where the research/need is applicable to that geography. That means it needs to be addressed in that area, or makes sense (*i.e.*, we wouldn't focus on forest loss to solar fields in urban areas). Figure 3 demonstrates that many of the questions and topics brough up by our members could and should be answered in urban waters.

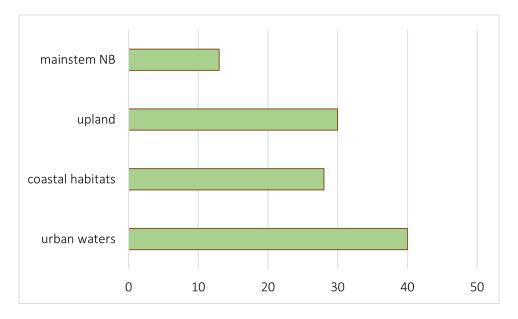

Figure 3. Summary of April 2023 Voting by Geography

Appendix A 2018 Draft Science Agenda

NARRAGANSETT BAY ESTUARY PROGRAM

235 Promenade Street, Suite 393 Providence, RI 02908 401-633-0550 info@nbep.org www.nbep.org

DRAFT – Narragansett Bay Estuary Program Science Strategy Draft as of 12/18/2018

Beginning in 2013, the Narragansett Bay Estuary Program started a process to compile and synthesize sound, peer-reviewed science to better understand the environmental condition of Narragansett Bay and its watershed. During this process, the Management Conference, particularly the Science Advisory Committee, and staff identified 24 environmental indicators of stress and condition (Figure 1). These indicator topics were used to discuss the state of the system as it is now and a retrospective look at trends. The culmination of this process was the 2017 *State of Narragansett Bay and Its Watershed*, a comprehensive, 500-page report detailing the status and trends of this bi-state watershed. The report provided for the first time a unified presentation of the best available data on environmental conditions across the entire bi-state watershed.

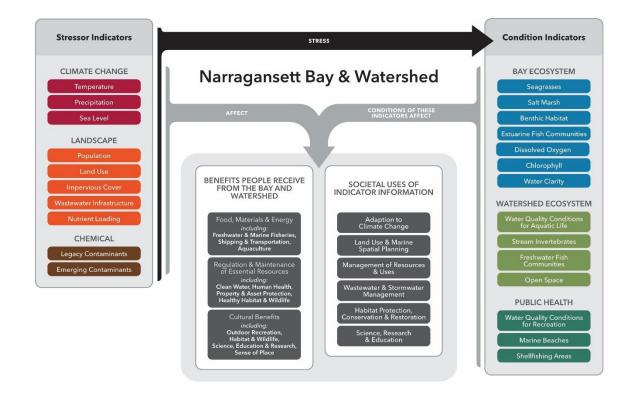

Figure 1. List of stressor and condition indicators. These indicator topics affect the benefits people receive from the Bay and Watershed and the societal uses of indicator information.

During this data discover and writing process, scientists, managers, and practitioners; the staff; and Science Advisory Committee members assembled lists of data gaps, assessment needs and research needs based on their expert opinions. Data gaps are areas (geographical or otherwise) which are true gaps in our knowledge of the indicator and system. Assessment needs are where the data exist to understand the issue at hand, but those data have not been analyzed or synthesized. Finally, research needs identify basic scientific questions which need to be answered through academic research.

When compiled as a whole, the data gaps and research needs from all 24 indicator chapters span approximately 12 pages in length. They detail every gap and need regardless of priority or current funding going towards those needs. The Science Advisory Committee agreed that the list needed to be prioritized and maintained. The needs were divided into their groups - data gaps, assessment needs, and research needs – and then each group was prioritized. These lists are maintained in a spreadsheet, with columns dedicated to notes and advances made (*i.e.*, work towards filling the gap or understanding the need). These spreadsheets were then synthesized further to show where the gaps and needs overlap, or are included in larger sub-topics. The results of that synthesis are included here, in this Science Strategy.

The aim of this Science Strategy is to translate key science needs identified through the 2017 *State of Narragansett Bay and Its Watershed* process into a concise and consensus-driven summary. These needs represent the gaps in our knowledge and the research and assessment needs required to further understand the environmental condition of Narragansett Bay. This document will channel future efforts towards the most pressing science needs. It will be shared with partners directly and attached to any future NBEP grant programs related to science. It is intended to be used by NBEP and partners to target funding, grants, external sources, and to be a vehicle of communication across the watershed.

The following Strategy is divided into 6 top needs, matching those identified in the *State of Narragansett Bay and Its Watershed*. These needs are: (1) Contaminants (both legacy and emerging); (2) Ecologically significant habitats and species; (3) Habitat restoration and enhancement; (4) Ecological flows (water dynamics); (5) Ecosystem functions (focusing on primary productivity and biology and chemical connectivity); and (6) Human health. These needs are equal and are not further prioritized.

One obvious missing top need is understanding the effects of climate change on our watershed. This need runs through the other needs, and research needs on the effects of climate change are included within each topic.

The NBEP Science Strategy will need to be continually assessed and re-evaluated as an iterative process. As the NBEP community funds (or receives funds for) gaps, assessments, or needs, these priorities will drop, allowing new ones to rise to the top. Therefore, every 5 years, this Science Strategy will be updated by the Science Advisory Committee to account for new topics and needs. The process to update the *State of Narragansett Bay and Its Watershed* will be used as the opportunity to review the data gaps and research needs.

Top Science Needs¹

Contaminants (both legacy and emerging)

Residual pollution from the watershed's history of manufacturing still plague our fish and shellfish. These legacy contaminants are passed up the food chain and eventually reach humans. Now, we are also beginning to understand that new pollutants, contaminants of emerging concern, can impact human health. These emerging contaminants are from pharmaceuticals or personal care products. We need to understand how pollutants, particularly legacy contaminants and emerging contaminants, will impact human health. Specifically, need to assess the levels of metal contamination in freshwater and estuarine water fish and shellfish and look for hotspots for contamination to better protect human health.

Ecological significant habitats and species

The watershed has key habitats that need to be monitored, such as sea grass, salt marsh, and the benthic habitats. Firstly, we need to implement or augment existing monitoring strategies, particularly for seagrasses and salt marshes. Then, understanding how these habitats will respond to the changes in climate and eutrophication is key to improving habitat resilience throughout the watershed.

Habitat restoration and enhancement

Restoration and enhancement projects are always underway throughout the watershed. These projects aim to restore natural capacity or improve ecosystem services of key habitats. Currently, NBEP is creating a Habitat Restoration and Protection Mapping Tool to assess restoration and enhancement activities already implemented within the watershed to better understand what needs to be done and where. A fundamental need is to also monitor and assess these activities to know if they are working properly, and create adaptive management strategies to ensure the projects longevity.

Ecological flows (water dynamics)

The water budget is an important piece to understand about the Narragansett Bay watershed. Key links between ecology and physical processes need to be understood so that we may be able to track and monitor any changes to the system, like sea level rise or other climate change impacts. Groundwater, drinking water sources, flood plains, and wastewater treatment (particularly onsite systems) are under threat from rising seas. We have models to understand these impacts (i.e. STORMtools), but they need to be applied equally across the watershed. These models rely on understanding basic climate trends, such as the changes to air and water temperature, and the frequency, amount, seasonality, and type of precipitation with time.

Ecosystem functions (focusing on primary productivity and biology and chemical connectivity)

Ecosystem functions, particularly those associated with nutrient dynamics and primary productivity need understanding. Recently, nutrient loading to the bay was reduced by almost half, and we need to understand how the ecosystem is responding. One avenue necessary to do that is through monitoring of water quality by sustaining the Narragansett Bay Fixed Site Monitoring Network. This network provides us with basic parameters which feed our understanding of ecosystem response to nutrient

¹ As noted, this science strategy stems from gaps and needs as identified in the 2017 *State of Narragansett Bay and its Watershed* report. Therefore, NBEP recognizes there are additional gaps and needs that were either missed in this assessment or were not relevant based on the selected indicators. For example, NBEP's report did not include social indicators and as such, no related gaps and needs are identified here despite the existence of such gaps and needs.

dynamics, physical changes to the water column, and key initial responses, such as phytoplankton blooms through increased chlorophyll production. These data can be used to continually develop and validate ecosystem and hydrodynamic models to further explore nutrient and dissolved oxygen dynamics. Spatial coverage of chlorophyll and water clarity data collection needs to be expanded to understand how nutrient dynamics are impacting the food web and water column. Existing datasets should be examined to inform future sampling plans. Additionally, we need to understand harmful algal and cyanobacteria blooms to understand how they form, and how they can be prevented, which protects human health. Finally, on land, we need to assess areas of high-density onsite systems to contribute pollutants to the watershed and by using soils and groundwater data.

Human Health (focusing on beaches)

Human health is an important aspect of a healthy watershed. We have touched upon this in the *Contaminants* and the *Ecosystem functions* categories. Here we touch upon one of the most economically important features of Narragansett Bay and its watershed – the beaches. The reasons behind beach closures need to be better understood and developing models for beach closures may help. Additionally, relating the beach assessments to water quality assessments of larger water bodies is missing.

collect data		Freshwater Connectivity	Need to understand how sediment and the contaminants in sediment are remobilized in dam removal or culvert removal/expansion
collect data	improve FW & SW habitat	Freshwater Connectivity	Understand how ecosystems transition from estuarine water to freshwater with dam or culvert removal to develop metrics for understanding what "done" looks like
collect data	ourthosize outsting data	Freshwater	Connect watershed and bay hydrologic models to fully understand how water moves throughout the region in response to climate change, restoration, or changes in infrastructure
	synthesize existing data	Connectivity	
collect data	synthesize existing data	Freshwater Ecosystems	Need to understand the inputs and stream ecosystem responses of generalized stress from watershed distrubance from legacy and existing land use
collect data		Freshwater Ecosystems	Develop methods to link watershed condition to stream biointegrity
collect data	synthesize existing data	Green Infrastrcuture	Model CSOs and flood-prone areas to target best place for green infrastructure
collect data	synthesize existing data	Contaminants	Understand the levels of legacy contaminants in fish/shellfish in estuarine and freshwaters
collect data		Contaminants	Understand the levels of emerging contaminants in fish/shellfish in estuarine and freshwaters
collect data		Contaminants	Understand how contaminants will become more/less bioavailable under changing pH and temperature conditions

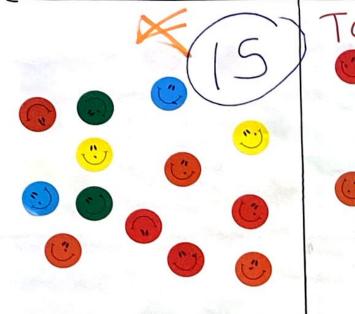

Categories		Science/Research Need	
SAC Topic Area (derived from 4/24 meeting)	SAC Topic Area (derived from 4/24 meeting) (secondary)	Topic Area	<u>Goal</u> : Each line is a specific science/research need
collect data		Contaminants	Understand how microplastics travels through the ecosystem
collect data		Contaminants	Understand the impacts of tire rubber fragments on waters near roadways
collect data	improve FW & SW habitat		Explore which organisms can "clean" the water of contaminants, but not be harvested for consumption
collect data		Mount Hope Bay & Sakonnet	Collect nutrient data in a manner that is comparable to ways data are collected currently
collect data	synthesize existing data	Nutrients	Update nutrient budget to include offshore component
collect data	synthesize existing data	Nutrients	Create a more accurate assessment of nonpoint source nutrient contributions
collect data	synthesize existing data	Rare Species/Wildlife	Understand where key rare species are located in the region
collect data		Rare Species/Wildlife	Unite, update existing information from Wildlife Action Plans to focus on critically important habitats
collect data		Access to Nature	Understand potential exposures to contamination from sediment, water, and air at urban beaches
collect data	share information widely	Access to Nature	Understand how people are using urban waters and pairing it with bio-physical data to understand the "health" of the water/air/sediment
collect data	share information widely	Access to Nature	Understand how people are accessing nature throughout the watershed, and what activities are they doing when in nature
collect data	share information widely	Stories	Develop ways to get more community buy-in for restorations
improve FW & SW habitat		Seagrass	Identify areas for restoration by updating models

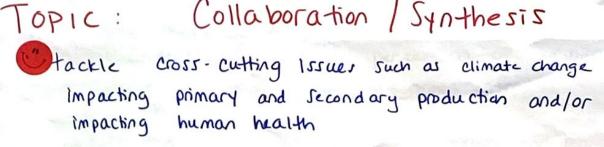

Categories		Science/Research Need		
SAC Topic Area (derived from 4/24 meeting)	SAC Topic Area (derived from 4/24 meeting) (secondary)	Topic Area	<u>Goal</u> : Each line is a specific science/research need	
	maintain/update			
improve FW & SW habitat	monitoring	Seagrass	Understand consequences of restoration	
		Permitting	Need to assess ways to permit shellfish restoration projects so they are not grouped	
improve FW & SW habitat		Challenges	with aquaculture site leases	
		Permitting		
improve FW & SW habitat		Challenges	Streamline and understand permitting challenges for restoration projects in MA	
improve FW & SW habitat	share information widely	Collaborations/Synt hesis	CreateLiving Observatories. An example is Succotash Marsh - what researchers want to do their research there while the restoration is going on? This includes social scientists to understand how neighbors think about the restoration, or what it takes for people to be supportive of these restorations.	
		Phytoplankton and		
analysis/modeling	synthesize existing data	Seaweed	Monitor harmful algal blooms (HABs), nuisance algal blooms	
analysis/modeling analysis/modeling	collect data collect data	Seagrass Seagrass	Monitor seagrass, and understand the conditions needed to expand seagrass acreage Refine seagrass monitoring protocol	
analysis/modeling		Salt Marsh	Monitor salt marsh habitat; extend monitoring in restored areas	
analysis/modeling	improve FW & SW habitat		Continue to understand how large scale restoration (like thin-layer deposition) impacts the ecosystem as a whole, and what a maintenance schedule may look like, if needed	
		Freshwater	Improve monitoring of fish passage (upstream and downstream) to better prioritize	
analysis/modeling	synthesize existing data	Connectivity	dam removals, culvert replacements, or fish passage projects	
		Freshwater	Understand the consequences of restoration and connectivity on the ecosystem and	
analysis/modeling	share information widely	Connectivity	people	
analysis/modeling	improve FW & SW habitat	Freshwater Ecosystems	Expand cyanobacteria monitoring and develop ways to reduce cyanobacteria blooms	
analysis/modeling		Green Infrastrcuture	Continue to monitor success of green infrastructure projects throughout region	
analysis/modeling		Green Infrastrcuture	Create decision-based support tool to choose best management practices for a specific site	

Categories			Science/Research Need
SAC Topic Area (derived from 4/24 meeting)	SAC Topic Area (derived from 4/24 meeting) (secondary)	Topic Area	<u>Goal</u> : Each line is a specific science/research need
analysis/modeling		Green Infrastrcuture	Understand how green infrastructure works in different urban environments
analysis/modeling		Access to Nature	Optimize and implement more rapid bacterial detection techniques to prevent unnecessary beach closures
analysis/modeling	share information widely	Collaborations/Synt hesis	Need long-term monitoring to make sure projects and restorations are still working, and what the lifetime of the restorations are
N/A	N/A	Permitting Challenges	Need people who can provide technical assistance to independently verify restoration techniques are best for the site
share information widely	synthesize existing data	Collaborations/Synt hesis	Create guidebook for restoration techniques using a gradient of degradation before restoration. At each level of degradation, useful techniques would be listedn, and then show if degradation improves after restoration and by how much. Can also show how long it took to determine success.
share information widely		Stories	Develop mechanisms to share peer-reviewed information to a more "public" realm
share information widely		Stories	Develop better mechanisms for communities to learn about advisories (unsafe beaches, fishing, cyanobacteria, etc.)
synthesize existing data	collect data	Precipitation	Understand the frequency, amount and seasonality and type of precipitation over time
synthesize existing data	collect data	Precipitation	Understand the impacts of increased precipitation (amount and intensity) on existing infrastructure and new development
synthesize existing data	collect data	Sea Level	analyze impacts of sea level rise on groundwater, drinking water supplies, floodplains, and OWTS
synthesize existing data	collect data	Sea Level	Understand sea level rise trends in region
synthesize existing data	collect data	Temperature	Analyze air and water temperature trends for region
synthesize existing data	collect data	Climate Change	Understand how human health will be impacted through the combined impacts of climate change, nutrient changes, and eco/environmental toxicology
synthesize existing data	collect data	Climate Change	understand changes to ecosystem from climate change - how primary production will change, changes to shellfish (coastal ocean acidification) or fish populations

Categories			Science/Research Need
SAC Topic Area (derived from 4/24 meeting)	SAC Topic Area (derived from 4/24 meeting) (secondary)	Topic Area	<u>Goal</u> : Each line is a specific science/research need
		Stormwater/non-	
		point source	
synthesize existing data	collect data	pollution	Understand how stormwater and hydrology impacts urban areas
	maintain/update	Phytoplankton and	Understand how winter-spring bloom impacts fisheries production and how that may
synthesize existing data	monitoring	Seaweed	be impacted by climate or other change in nutrient availability
	maintain/update	Estuarine	analyze water clarity information as part of larger water quality monitoring and
synthesize existing data	monitoring	Ecosystems	understanding
synthesize existing data		Contaminants	Identify "hot spots" for legacy and emerging contaminants in the watershed
			Develop "action levels" for drinking water and surface water for PFAS and other
synthesize existing data	collect data	Contaminants	emerging contaminants
		Mount Hope Bay &	
synthesize existing data		Sakonnet	What data are missing?
synthesize existing data	collect data	Nutrients	Refine nutrient budget to account for seasonality in inputs
			Understand the total amount of nutrients the bay can assimilate while keeping
			nutrient-driven hypoxia low, water clarity elevated, and supports primary and
synthesize existing data	collect data	Nutrients	secondary production
			Pull data sources together to answer larger complex questions - how are coastal
		Collaborations/Synt	habitats doing after large scale restorations are in place (such as the fisheries work in
synthesize existing data	share information widely	hesis	the Providence River)
		Collaborations/Synt	Understand stressor-relationships to use a stressor-response approach to develop
	share information widely	hesis	TMDLs or ecosystem-based management actions
Cells this color come from S	S&T Data gap, assessment n	eed, research need	

CHAPTER 1: PEOPLE

Create living observatories to develop Collaborations and more complete understanding of large-scale projects

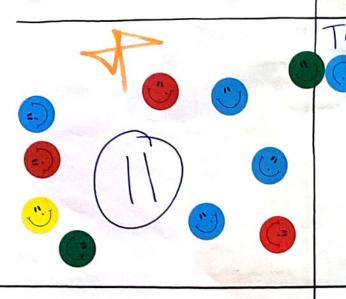

TOPIC: Information + Storytelling

- . Create guides for restoration techniques
- invest in long-term monitoring
- . develop mechanisms for more complete Community learning

TOPIC: Governance

- · Streamling permitting + guidance
- · provide technical assistance to independently verify sound restoration techniques

CHAPTER 2: WATER

0

TOPIC: POINT + NONPOINT Source Pollution quantify point and nonpoint source pollution better understand public's perception of stormwater . understand best places to site green infrastructure projects

- . update nutrient budget to include offshore and reasonality
- expand modeling to understand total amount of nutrients bay can assimilate

TOPIC: Trash and Contaminants

- . develop 'action levels' for key contaminants
- · identify 'not spots' of contamination
- · understand how climate impacts contaminant mobilization

Topic: Sea level rise and flooding

- existing infrastructure and new development
- people/infrastructure versus other options

TOPIC: Water supply

- · update water budget to understand groundwater/ surface water relationships
- . understand how pollutants transferred through ground water

	HAPTER 3: HABITAT AND WILDLIFE
0	TOPIC: LAND USE understand impact of renewable energy on the landscape
	TOPIC: Freshwater Living resources improve monitoring to better prioritize fish passage and habitat connectivity projects understand transition from freshwater to estuarine systems with dam/culvert removal and passage projects connect watershed and bay hydrologic models expand cyano bacteria monitoring and research to reduce blooms
	TOPIC: Estuarine living resources understand how undersea cables impact benthos understand primary and secondary production changes to bay under climate change and nutrient changes monitor/understand harmful/nuisance algal blooms understand impacts of shellfish restoration monitor seagrass and understand conditions needed to expand acreage monitor salt marsh and understand marsh migration and enhance potential understand consequences of large-scale restoration on ecosystem
	TOPIC: Wildlife · Update existing information for wildlife action plans and other resources

CHAPTER 4: PUBLIC SPACES
